Sample Problem: Ideal Gas Calculation

Problem:

Calculate the volume of 44 g of carbon dioxide (CO₂) at 27 °C and 2.96 atm.

Solution:

Start with ideal gas law:

$$P V = n R T$$

(Ideal gas law should be an equation that you know completely! It applies to GASES not liquids or solids. It is your path to a gas density - mass or molar density ($n/V = RT/P$). Ideality is valid for high T and low P. Ambient T and P easily satisfy these criteria. I would STRONGLY discourage you from using or remembering the "22.4 L per mol" style information as it is rare that one also remembers what T and P this is valid at thus it introduces unnecessary risk.)

Rearrange to isolate volume.

$$V = \frac{n R T}{P}$$

First determine the number of moles of carbon dioxide.

$$n = \frac{m}{MW_t}$$

$$n = \frac{44 \text{ g}_{CO_2}}{44 \frac{\text{g}_{CO_2}}{\text{mol}_{CO_2}}} = 1.0 \text{ mol}_{CO_2}$$

Enter the value of each parameter into the equation complete with its units.

$$V = \left(\frac{1.0 \text{ mol}_{CO_2} * 8.314 \text{ Pa m}^3 / (\text{mol K}) * (273.15 + 27) \text{ K}}{2.96 \text{ atm} * 101325 \text{ Pa/atm}} \right)$$

(There are lots of different "R values" depending on the units. I find it easier to just remember one R with its units. I find 8.314 Pa m³/(mol K) the best to remember as it is SI. It also works in energy terms too as a Pa.m³ is also a Joule leading to 8.314 J/(mol K). Some individuals use a value of R in mass units rather than molar units. This requires a different value for R for each compound. These different R-values in mass units are just different due to the different molar mass values for each compound. It is just easier to work with R in molar units and use molar mass for the role of converting between mass and moles.)

Calculate and reconcile units.

$$V = 0.00832 \text{ m}_{CO_2}^3$$

Sample Problem: Ideal Gas Calculations

Judgment check – ambient air has a density of about 1.2 kg/m^3 . We have about $1/30^{\text{th}}$ of 1.2 kg and 3 times the pressure; thus we should expect about $1/90^{\text{th}}$ of 1.0 m^3 . This provides or confirms the calculated value is approximately correct.

Therefore, the volume of 44 g of carbon dioxide at $27 \text{ }^\circ\text{C}$ and 2.96 atm is 0.0083 m^3 assuming ideal gas behaviour prevails.
